2-1 Journal: Code Review Journal

Part 1:

1. What is a code review?

- A code review is an examination of source code. Usually, code reviews are done by a developer or developers that did not write the code, much like doing a peer-review for a writing assignment.

2. Why is it an important practice for computer science professionals?

- This process is important because it allows for feedback to be given to the developer and fosters a collaborative environment. Additionally, the reviewer could catch mistakes and vulnerabilities that the developer missed while writing the code.

3. What are some code review best practices that you read about in the resources that are crucial to include in a code review? Include when a code review should occur in the development process with a rationale as to why.

- Some best practices include breaking down the code into smaller portions to review, limited review duration, feedback and automated testing.
- Code reviews should take place once the code is functionally complete to avoid any planned changes that may occur if done too early in the process. It is also important to do

this before any code is committed to a production environment to avoid potential critical errors and elevated costs to correct.

Part 2:

4. What software have you chosen to use to record your code review?

- I am going to be using Clipchamp to record my code review. I am using a Linux computer so I can use it through the Online Student Resources page.

5. Describe your approach to creating an outline or writing a script for your code review for each of the three categories that you will be reviewing based on the rubric as well as the code review checklist.

- I will be approaching this by creating an outline of topics for each artifact and category. I have found that I can better articulate my speech without a strict script to follow when I am explaining code and technical concepts.
